7. COMMUNICATION INTERFACE

7.1 3-wire Serial Interface

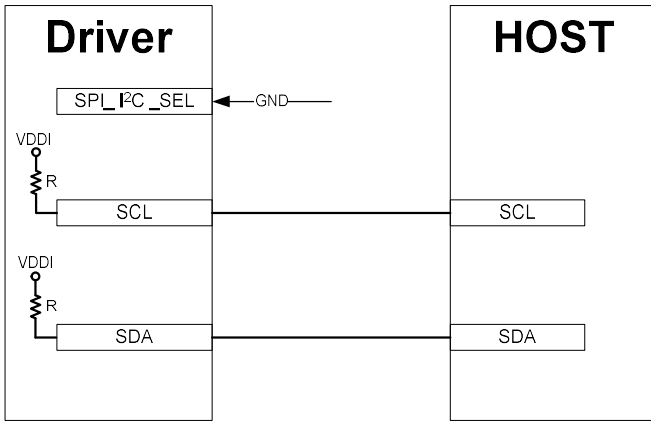

R/W: Read/Write mode control bit.  
 R/W=1: Read mode  
 R/W=0: Write mode

- a. Each serial command consists of 16 bits of data which is loaded one bit a time at the rising edge of serial clock SCL.
- b. Command loading operation starts from the falling edge of CS and is completed at the next rising edge of CS.
- c. The serial control block is operational after power on reset, but commands are established by the VSYNC signal. If command is transferred multiple times for the same register, the last command before the VSYNC signal is valid.
- d. If less than 16 bits of SCL are input while CS is low, the transferred data is ignored.
- e. If 16 bits or more of SCL are input while CS is low, the previous 16 bits of transferred data before then rising edge of CS pulse are valid data.
- f. Serial block operates with the SCL clock
- g. Serial data can be accepted in the power save mode.
- h. After power on reset or GRB reset, it is required 100ms delay to begin SPI communication.

### 7.2 I<sup>2</sup>C Interface

The I<sup>2</sup>C Interface is bi-directional two-line communication between different ICs or modules. The two lines are a Serial Data line (SDA) and a Serial Clock line (SCL). Both lines have built-in pull up resistor which drives SDA and SCL to high when the bus is not busy. Data transfer can be initiated only when the bus is not busy.

#### 7.2.1 Bit Transfer

One data bit is transferred during each clock pulse. The data on the SDA line must remain stable during the HIGH period of the clock pulse because changes of SDA line at this time will be interpreted as START or STOP. Bit transfer is illustrated as follows.

#### 7.2.2 START and STOP Conditions

Both SDA and SCL lines remain HIGH when the bus is not busy. A HIGH-to-LOW transition of SDA, while SCL is HIGH is defined as the START condition (S). A LOW-to-HIGH transition of SDA while SCL is HIGH is defined as the STOP condition (P). The START and STOP conditions are illustrated as follows.

### 7.2.3 System Configuration

The system configuration is illustrated above and some word-definitions are explained below:

- a. Transmitter: the device which sends the data to the bus.
- b. Receiver: the device which receives the data from the bus.
- c. Master: the device which initiates a transfer generates clock signals and terminates a transfer.
- d. Slave: the device which is addressed by a master.
- e. Multi-Master: more than one master can attempt to control the bus at the same time without corrupting the message.
- f. Arbitration: the procedure to ensure that, if more than one master tries to control the bus simultaneously, only one is allowed to do so and the message is not corrupted.
- g. Synchronization: procedure to synchronize the clock signals of two or more devices.

### 7.2.4 Acknowledgment

Each byte of eight bits is followed by an acknowledge-bit. The acknowledge-bit is a HIGH signal put on SDA by the transmitter during the time when the master generates an extra acknowledge-related clock pulse. A slave receiver which is addressed must generate an acknowledge-bit after the reception of each byte. A master receiver must also generate an acknowledge-bit after the reception of each byte that has been clocked out of the slave transmitter. The device that acknowledges must pull-down the SDA line during the acknowledge-clock pulse, so that the SDA line is stable LOW during the HIGH period of the acknowledge-related clock pulse (set-up and hold times must be taken into consideration). A master receiver must signal an end-of-data to the slave transmitter by not generating an acknowledge-bit on the last byte that has been clocked out of the slave. In this event the transmitter must leave the data line HIGH to enable the master to generate a STOP condition. Acknowledgement on the I<sup>2</sup>C Interface is illustrated as follows.

### 7.2.5 I<sup>2</sup>C Interface Protocol

The driver supports command/data write to addressed slaves on the bus. Before any data is transmitted on the I<sup>2</sup>C Interface, the device which should respond is addressed first. The default slave address is 0111100b and the three times I<sup>2</sup>C address could be OTP programming.

The sequence is initiated with a START condition (S) from the I<sup>2</sup>C Interface master, which is followed by the slave address. All slaves with the corresponding address acknowledge in parallel, all the others will ignore the I<sup>2</sup>C Interface transfer. After acknowledgement, one or more command or data words are followed and define the status of the addressed slaves.

Only the addressed slave makes the acknowledgement after each byte. At the end of the transmission the bus master issues a STOP condition (P). If no acknowledge is generated by the master after a byte, the driver stops transferring data to the master. The register write/ read transference sequence are described as follows.

#### Write Mode (R/W="0")

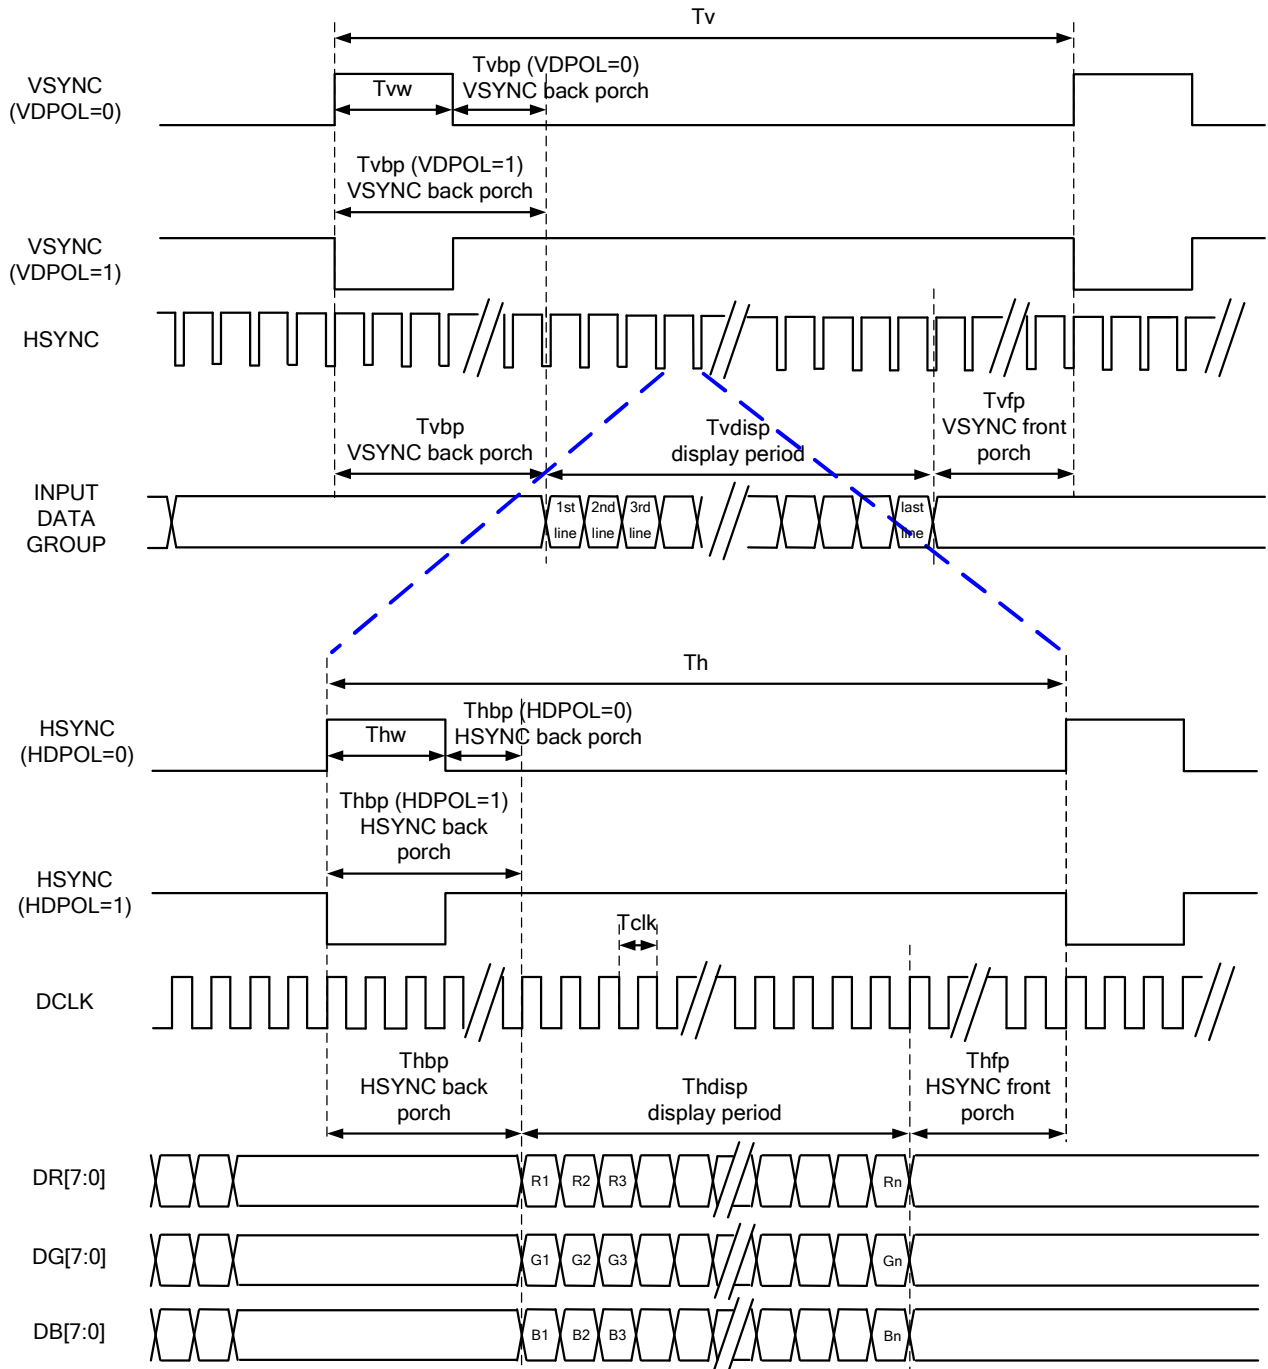

#### Read Mode (R/W="1")

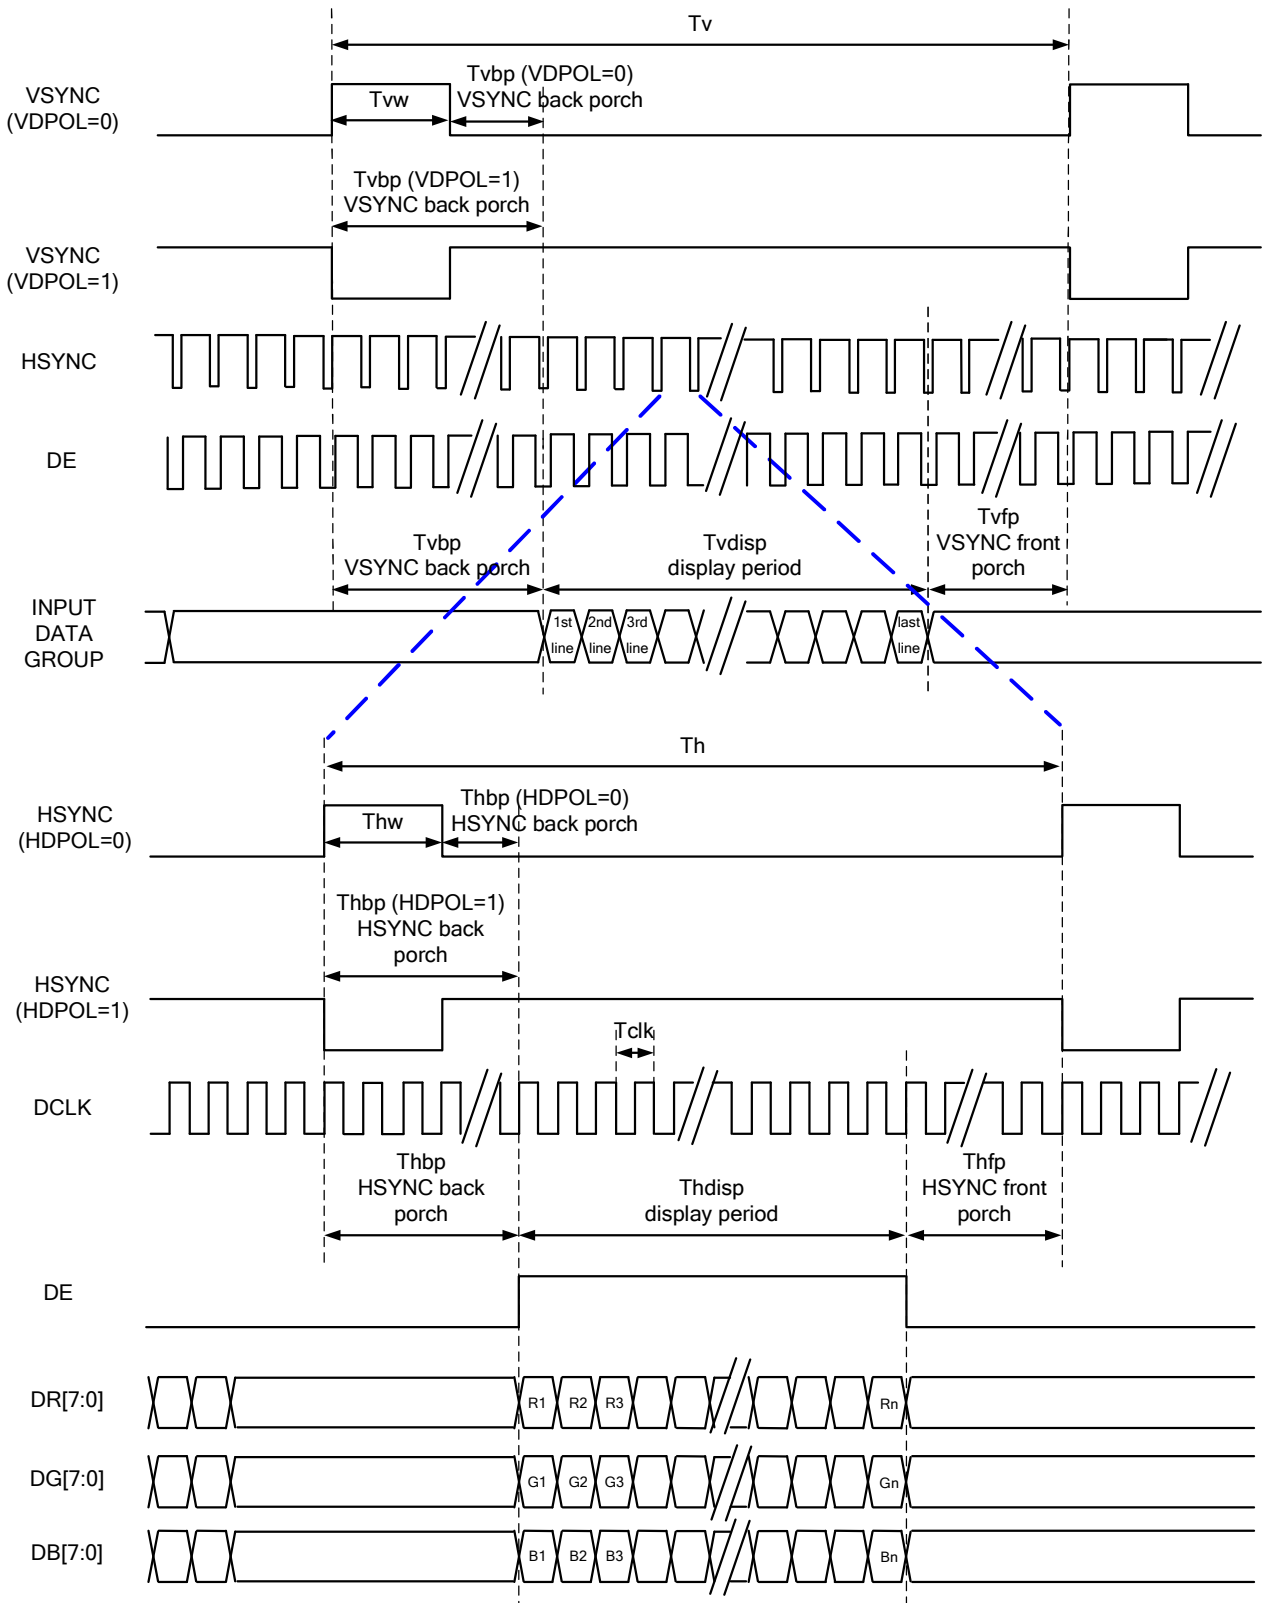

- S: start condition

## 9. ELECTRICAL SPECIFICATIONS

### 9.1 Absolute Maximum Ratings

Item	Symbol	Rating	Unit
Power Supply Voltage	VDD	- 0.3 ~ +4.0	V
IO Supply Voltage	VDDI	- 0.3 ~ +4.0	V
Charge Pump Supply Voltage	PVDD	- 0.3 ~ +4.0	V

Operating Temperature Range	TOPR	-30 ~ +85	°C
Storage Temperature Range	TSTG	-40 ~ +125	°C

*Note:*

1. That the stress exceeds the Limiting Value listed above it may cause the driver IC permanent damage. These values are for stress only. IC should be operated under the DC/AC Characteristic conditions for normal operation. If these conditions are not met, IC operation may be error and the reliability may be deteriorated.
2. Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to VSS unless otherwise noted.
3. Insure the voltage levels of VDDI, VDD, PVDD always matches the correct relation:  

$$3.0V \leq VDDI \leq VDD = PVDD \leq 3.6V$$
4. VIN should be less than or equal to 3.6V. (VIN ≤ 3.6V)

**15. COLOR FILTER ARRANGEMENT**

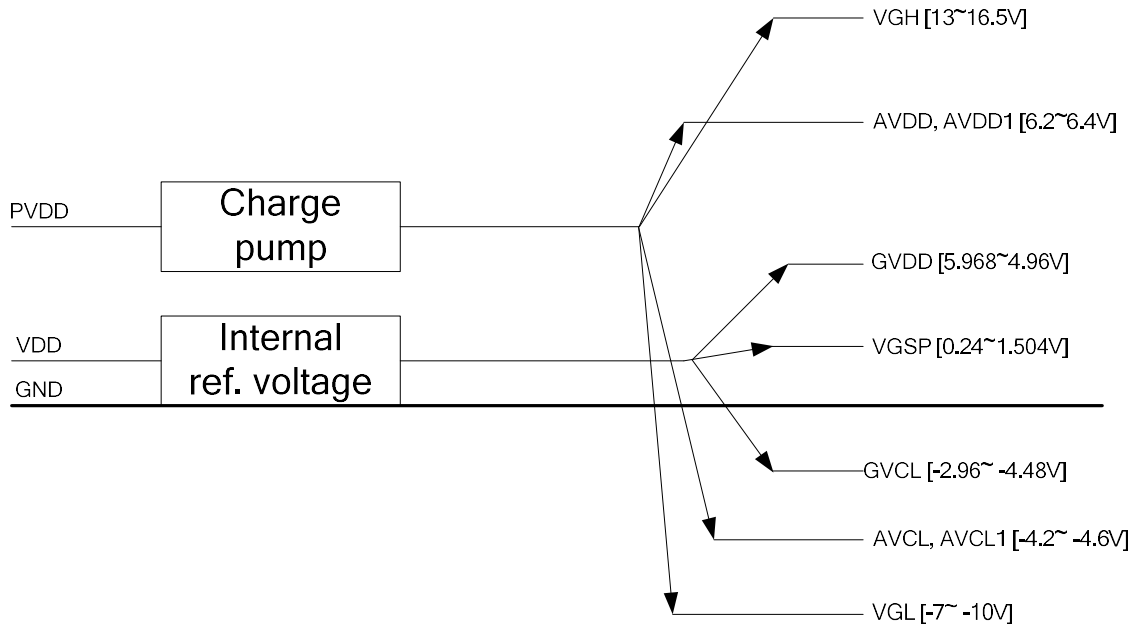

The driver supports the stripe color filter of dual-gate application. The color filter arrangement on panel is shown below.

16. POWER STRUCTURE

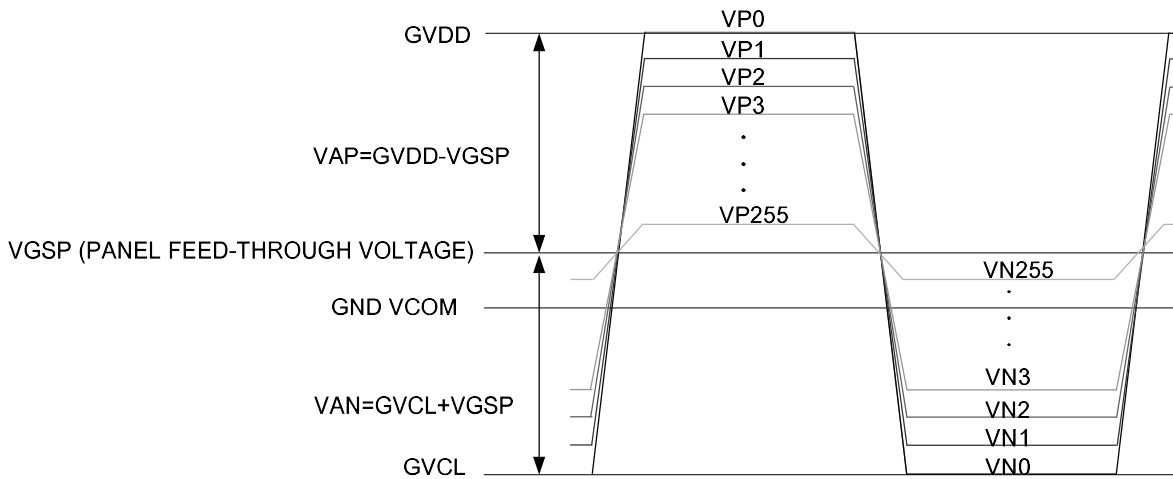

16.1 Voltage Generation

The following figure is relations of analog voltage

16.2 Source Voltage Relations

The relations between VCOM and source voltage is shown as below:

Note: The IC source support maximum LC driving voltage VAP (VAN):  $5.224V [(GVDD - VGSP) = (VGSP - GVCL) = (GVDD - GVCL) / 2]$ .

The driver compensates the panel feed-through voltage = VGS
